

ADTA 5900/5560: Assignments

Important Notes

Thuan L Nguyen, PhD

1. Overview

To build, train, and test neural networks, the student needs to write Python code in Jupyter Notebook documents and run the code in the remote server. While **the code is running**, the system **displays the details of the results of each epoch**. It **takes some time** for the training process to **finish all the epochs, maybe 100 or more**.

What we see in the cell of the outputs of training the models actually happens in the remote server, not in the local computing device, i.e., a desktop or laptop. Therefore, the **local computer may hibernate** due to “being idle for a long time.”

When **the local computer hibernates**, it **kills all the connections to the network and the remote server**, which in turn **freezes displaying the progress of the training process**, i.e., stop printing the results of each epoch.

2. A Suggested Solution

The student should **adjust the power management** of the **local computer** so that it **never** “sleep.”

3. Another Suggested Solution

If after adjusting the power management of the local computer, the problem still occurs, i.e., the computing activities of cloud users in the same zone are too “busy,” the student can **reduce the number of epochs** from **100** to **75** or **50** or even **fewer** so that he/she can **finish the task and get the results**.

After that, he/she can **try again with 100 epochs** to see **if the situation has been improved**.
